THINK OF S.W. AND H.W. IMPLEMENTATION

Multiplier is expensive so when we have FIR w/ symmetry we can pre-add before multiplying. (use FIR for linear phase req., otherwise use IIR).

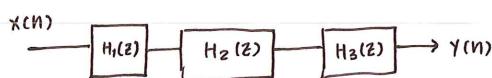

Cycles are taking up silicon real estate.

cascaded structure

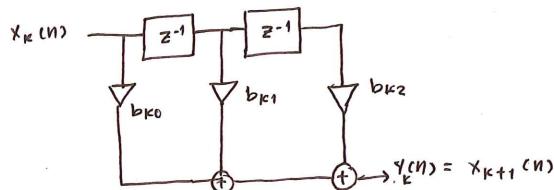

$$H(z) = b_{k0} + b_{k1}z^{-1} + b_{k2}z^{-2}$$

sections

$$H(z) = \prod_{k=1}^K H_k(z)$$

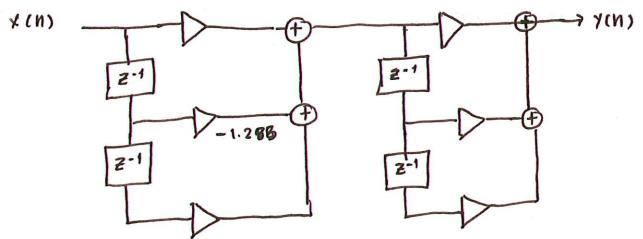

Each section 2nd order (IIR, second order bi quad)

$$H(z) = 1 - 2.018z^{-1} + 3.97z^{-2} - 2.18z^{-3} + z^{-4}$$

$$H(z) = H_1(z) \cdot H_2(z) = (1 - 1.205z^{-1} + z^{-2})(1 - 1.5337z^{-1} + z^{-2})$$

parallel structures

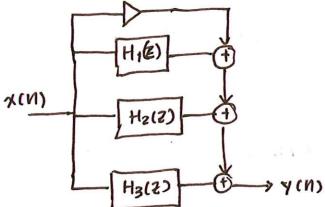

$$H(z) = C + \sum_{k=1}^N \frac{A_k}{1 + P_k z^{-1}}$$

$$C = \frac{b_N}{a_N}$$

PARTIAL FRACTION EXPANSION

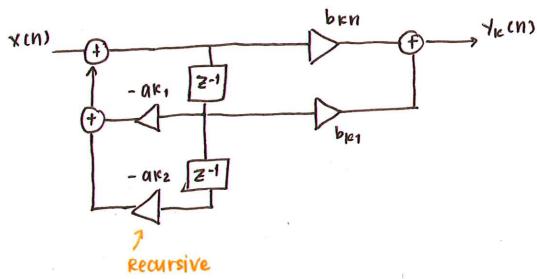

we get complex poles,

$$H_k(z) = \frac{b_{k0} + b_{k1}z^{-1}}{1 + a_{k1}z^{-1} + a_{k2}z^{-2}}$$

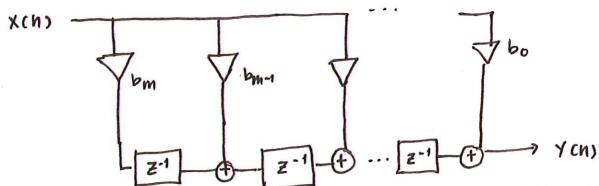

2nd order section

FOR second order section,

FIR transpose structure

D-flip flops also expensive in HW implementation.

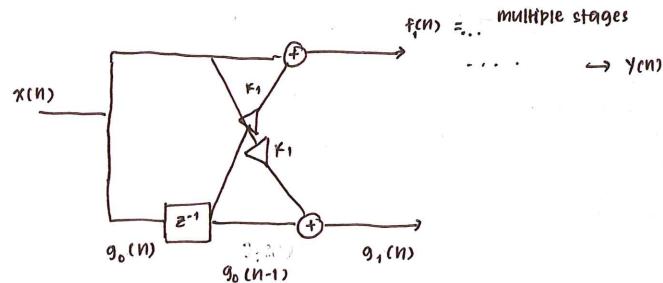

Let $w_m(n) = b_m x(n)$ at each stage

$$w_k(n) = w_{k+1}(n-1) + b_k x(n)$$

then

$$y(n) = w_1(n-1) + b_0 x(n)$$

FIR Lattice Structures

$$y(n) = x(n) + \sum_{k=1}^m \alpha_k(n-k) x(n-k)$$

$M = 1$

$$y(n) = x(n) + \alpha_1(n) x(n-1)$$

$M = 2$

$$y(n) = x(n) + \alpha_2(n) x(n-1) + \alpha_1(n) x(n-2)$$

$$f_1(n) = x(n) + k_1 x(n-1)$$

$$y_1(n) = k_1 x(n) + x(n-1)$$

cascade

$$f_2(n) = f_1(n) + k_2 y_1(n-1)$$

$$g_2(n) = k_2 f_1(n) + g_1(n-1)$$

$f_2(n)$ by substitution,

$$\begin{aligned} y(n) &= f_2(n) \\ &= x(n) + k_1 x(n-1) + k_2 (x(n-2)) \\ &= x(n) + k_1(1 + k_2) x(n-1) + k_2 x(n-2) \end{aligned}$$

compare: $k_2 = \alpha_2(2)$

$$k_1 = \frac{\alpha_2(1)}{1 + \alpha_2(2)}$$

Optimum Equiripple FIR Filter Design

Step by Step Process
By: The Graduates
EE410 HW#9

Why choose this more complicated method?

- Precise control over critical frequencies
- Weighted approximation error spread evenly over frequency response of filter

Definitions

- $H_{dr}(\omega)$: desired filter
- Assuming Low Pass Type 1 Filter, $Q(\omega) = 1$
- Normalized weighting function
 $W(\omega) = 62/81$, in the passband
 $W(\omega) = 1$, in the stopband
- Best Weighted Approximation to $H_{dr}(w)$:

$$P(\omega) = \sum \alpha(k)x^k, \quad x = \cos(\omega)$$

Remez Algorithm

- Compute δ analytically (ω_n in the range: $0 \leq \pi / (M+1) < \pi$):

$$\delta = \frac{p_0 \hat{H}_{dr}(\omega_0) + p_1 \hat{H}_{dr}(\omega_1) + \dots + p_{L-1} \hat{H}_{dr}(\omega_{L-1})}{W(\omega_0) + W(\omega_1) + \dots + W(\omega_{L-1})} \quad p_k = \prod_{m=0}^{L-1} \frac{1}{\cos \omega_m - \cos \omega_k}$$

- Use δ to find $P(\omega_n)$:

$$P(\omega_n) = H_{dr}(\omega_n) - \frac{(-1)^n \delta}{W(\omega_n)}, n = 0, 1, \dots, L+1$$

Algorithm (Contd.)

- Use Lagrange Interpolation to find $P(\omega)$:

$$P(\omega) = \frac{\sum_{k=0}^L P(\omega_k) [\beta_k / (\omega - \omega_k)]}{\sum_{k=0}^L [\beta_k / (\omega - \omega_k)]}$$

$$\beta_k = \prod_{\substack{n=0 \\ n \neq k}}^L \frac{1}{\omega_k - \omega_n}$$

Algorithm (Contd.)

- Compute the Error Function:

$$E(\omega) = W(\omega)[H_{dr}(\omega) - P(\omega)]$$

- If $|E(\omega)| \geq \delta$
then, select a new set of frequencies
corresponding to $L+2$ largest peaks and
repeat computations beginning with δ .
- Repeat process, until $|E(\omega)| \leq \delta$

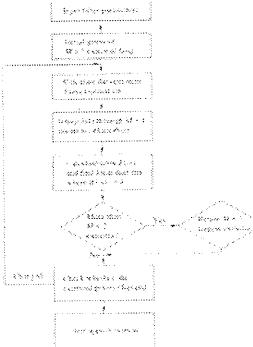

Finally,

- Optimal solution is reached:

$$H_d(\omega) = P(\omega)$$

- Use Table 10.5 to find $h(n)$

Parks&McClellan Program

Matlab Algorithm

- Design parameters
 - 1)
 - Critical frequencies: ω_p and ω_s
 - 2)
 - Passband Ripple (R_p) and Stopband Attenuation (A_s)
 - or-
 - Passband Tolerance (δ_1) and Stopband Tolerance (δ_2)

$$R_p = -20 \log_{10} \frac{1 - \delta_1}{1 + \delta_1}$$

$$A_s = -20 \log_{10} \frac{\delta_2}{1 + \delta_1}$$

Side Note: Calculating filter order

- Can we use formula given in class 4.5dB/bit and our desired stopband attenuation to calculate the order number instead of using firpmord() matlab function

[n,fo,ao,w] = FIRPMORD(f,a,dev)

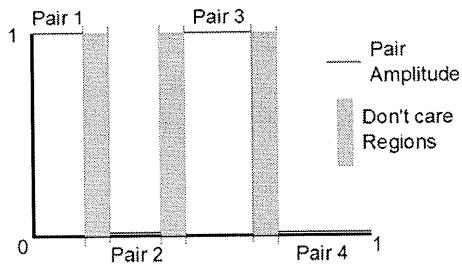

- We use this to calculate our initial order number value for filter, and all inputs for firpm.
- f = vector of cutoff frequencies
 - f = $[\omega_{p1} \ \omega_{s1} \ \omega_{s2} \ \omega_{p2} \ \omega_{p3} \ \omega_{s3}]$;
 - Length of F must be even
- a = vector specifying the desired function's amplitude
 - a = [1 0 1 0];
- dev = $[\delta_1 \ \delta_2 \ \delta_1 \ \delta_2]$; %maximum allowable ripple size

b = FIRPM(n,f,a,w)

- n = order of filter
- f = PAIRS of normalized frequency points between 0 and 1, where 1 corresponds to the Nyquist frequency. Must be even.
 - f = [0 ω_{p1} ω_{s1} ω_{s2} ω_{p2} ω_{p3} ω_{s3} 1];
- a = desired amplitude pairs which correspond to the frequency pairs. Must be same size as f
 - a = [1 1 0 0 1 1 0 0];
- w = weights assign an importance factor for the accuracy to each f pair relative to other pairs
 - w = [1 2 1 2]; % half the length of f

Figure – Plotting f and a (firpm)

$f = [0 \ \omega_{p1} \ \omega_{s1} \ \omega_{s2} \ \omega_{p2} \ \omega_{p3} \ \omega_{s3} \ 1];$
 $a = [1 \ 1 \ 0 \ 0 \ 1 \ 1 \ 0 \ 0];$

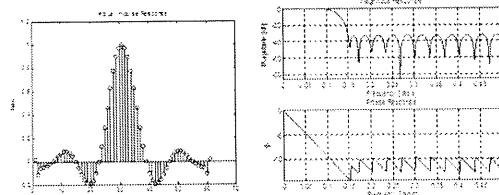

Check if correct attenuation has been reached.

- Convert discrete domain impulse response (from firpm function) into frequency domain impulse response.
- Compare:
 - IF: Maximum stopband attenuation of our optimized impulse response is more than our desired stopband attenuation, THEN increment the order and re-run firpm UNTIL less than

6.5 THE FREQUENCY RESPONSE OF DISCRETE-TIME LTI SYSTEMS

A. Frequency Response:

In Sec. 2.6 we showed that the output $y[n]$ of a discrete-time LTI system equals the convolution of the input $x[n]$ with the impulse response $h[n]$; that is,

$$y[n] = x[n] * h[n] \quad (6.67)$$

Applying the convolution property (6.58), we obtain

$$Y(\Omega) = X(\Omega)H(\Omega) \quad (6.68)$$

TB 2.30) FOR $y(n)$, $n \geq 0$

$$y(n) - 3y(n-1) - 4y(n-2) = x(n) + 2x(n-1)$$

$$\text{where } x(n) = 4^n u(n)$$

Determine the response.

① We assume the solution to the homogeneous eq.

$$y_h(n) = \lambda^n$$

thus the characteristic eq.

$$\lambda^n - 3\lambda^{n-1} - 4\lambda^{n-2} = 0$$

$$\lambda^{n-2}(\lambda^2 - 3\lambda - 4) = 0$$

$$(\lambda-1)(\lambda+4) = 0$$

$$\lambda_1 = -1, \lambda_2 = 4$$

$$\therefore y_h = c_1 \lambda_1^n + c_2 \lambda_2^n = c_1 (-1)^n + c_2 (4)^n$$

② The particular solution is of the form,

$$y_p(n) = Kn 4^n u(n)$$

Substituting $y_p(n)$ and $x(n)$ into the original expression,

$$Kn 4^n u(n) - 3K(n-1) 4^{n-1} u(n-1) - 4K(n-2) 4^{n-2} u(n-2) = 4^n u(n) + 2[4^{n-1} u(n-1)]$$

Evaluate for K by selecting $n=2$, to maintain unit step terms.

$$32Ku(2) - 12Ku(1) = 16u(2) + 8u(1)$$
$$32K - 12K = 16 + 8 \Rightarrow K(20) = 24 \Rightarrow K = \frac{6}{5}$$

$$\therefore y_p(n) = \frac{6}{5} n 4^n u(n)$$

$$③ y_t = y_h + y_p = c_1 (-1)^n + c_2 (4)^n + \frac{6}{5} n 4^n u(n)$$

④ APPLY initial conditions, where $n=0, n=1$

FOR original equation:

$$y(0) = 3y(-1) + 4y(-2) + x(0) + 2x(-1)$$

$$y(1) = 3y(0) + 4y(-1) + x(1) + 2x(0)$$

$$y(0) = 4^0 u(0) = 4^0 = 1$$

$$y(-1) = 4^{-1} u(-1) = 4^{-1} \cdot 0 = 0$$

$$x(1) = 4^1 u(1) = 4$$

$$\therefore y(0) = 3y(-1) + 4y(-2) + 1$$

$$y(1) = 3y(0) + 4y(-1) + 4 + 2 = 3y(0) + 4y(-1) + 6$$

$$= 3[3y(-1) + 4y(-2) + 1] + 4y(-1) + 6$$

TB1.10) $y_a(t) = 3 \cos 600\pi t + 2 \cos 1800\pi t$
 Rate = 10,000 bits/s Levels = 1024 [binary numbers]

(A) SAMPLING FREQ.
 From 1.4.5, we need to know number of bits from coder.

$$\text{Number of bits} = \log_2 1024 = 10 \text{ bits}$$

$$F_s = \frac{\text{Rate}}{\text{Number of bits}} = \frac{10,000 \text{ bits/s}}{10 \text{ bits}} = 1,000 \frac{1}{s} = 1 \text{ kHz} //$$

Folding frequency:

$$F_f = \frac{F_s}{2} = 500 \text{ Hz} //$$

$$(B) \quad F_1 = \frac{f_1}{2} = 300 \text{ Hz} \quad F_2 = 900 \text{ Hz}$$

$$F_{\max} = F_2$$

$$F_N = 2F_2 = 1800 \text{ Hz} //$$

NYQUIST FREQUENCY

(C) $F_s = 1000 \text{ Hz}$ $F_s > 2F_{\max}$ where $2F_{\max} = 2000 \text{ Hz}$

$$\text{folding frequency} = \frac{F_s}{2} = 500 \text{ Hz}$$

$$x(n) = x_0(nT) = x_0\left(\frac{n}{F_s}\right)$$

$$x_0 = 3 \cos 60.0 \pi t + 2 \cos 180.0 \pi t$$

$$\frac{N}{F_s}$$

If $F_n > \frac{F_s}{2}$, aliasing will be observed.

$$x(n) = 3 \cos 2\pi \left(\frac{300}{1000}\right)n + 2 \cos 2\pi \left(\frac{900}{1000}\right)n$$

We need to make $F_2 < \frac{F_s}{2}$ (which is 500 Hz)

$$\text{for } F_2, \quad (1 - \frac{9}{10}) = \frac{1}{10}$$

$$x(n) = 3 \cos 2\pi \left(\frac{3}{10}\right)n + 2 \cos 2\pi \left(\frac{1}{10}\right)n$$

In other words, $f_1 = \frac{3}{10}$ and $f_2 = \frac{1}{10}$ //

(D) $\Delta = \frac{x_{\max} - x_{\min}}{1023} = \frac{5 - (-5)}{1023} = \frac{10}{1023}$

because $\cos_{\max} = 1$ and $\cos_{\min} = -1$ //

MB3.3) Determine analytically the DTFT.

$$(1) x(n) = 2(0.5)^n u(n+2)$$

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x(n) e^{-j\omega n}$$

when $n < -2$, $x(n) = 0$

$$\therefore X(e^{j\omega}) = 2 \left[0 + (0.5)^{-2} e^{-j2\omega} + (0.5)^{-1} e^{-j\omega} + \sum_{n=0}^{\infty} (0.5)^n e^{-j\omega n} \right]$$

For an infinite geometric series,

$$\sum_{n=0}^{\infty} (0.5)^n e^{-j\omega n} = \frac{(0.5e^{-j\omega})^{\infty} - 0}{(0.5e^{-j\omega}) - 1} = \frac{1}{1 - 0.5e^{-j\omega}}$$

$$\therefore X(e^{j\omega}) = 2 \left[(0.5)^{-2} e^{-j2\omega} + (0.5)^{-1} e^{-j\omega} + \frac{1}{1 - 0.5e^{-j\omega}} \right] //$$

$$(2) x(n) = (0.6)^{|n|} [u(n+10) - u(n-11)]$$

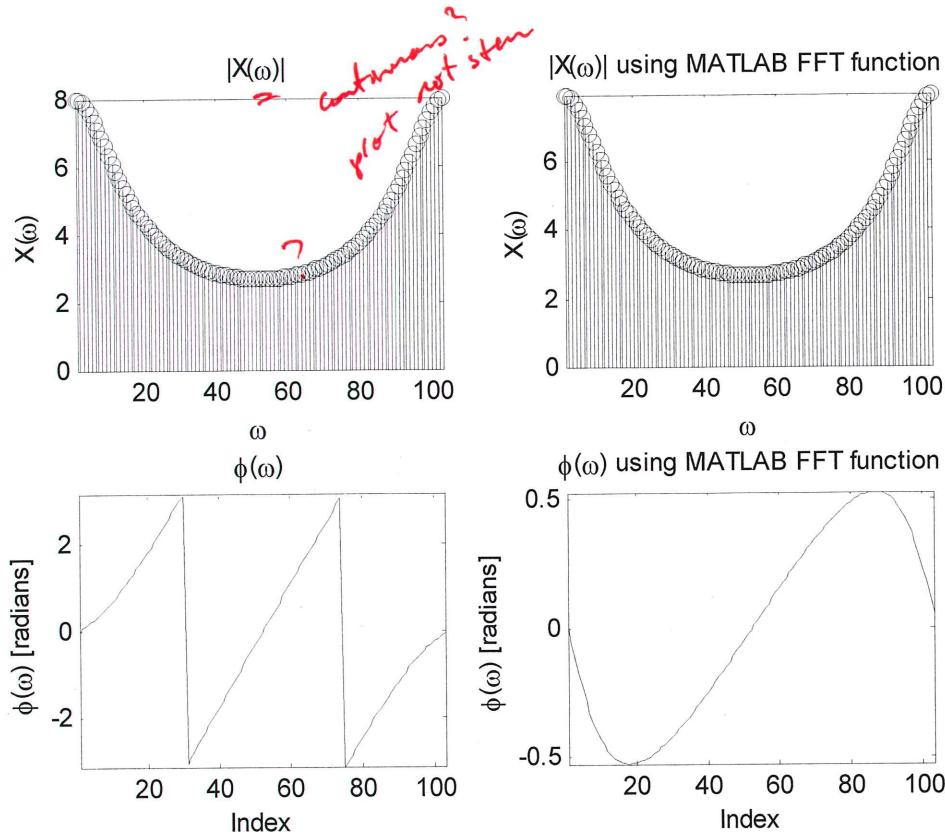

For $n < -10$ and $n > 11$, $x(n) = 0$

Since we use $|n|$,

$$X(e^{j\omega}) = \sum_{n=1}^{10} (0.6)^n e^{-j\omega n} + \sum_{n=0}^{11} (0.6)^n e^{-j\omega n}$$

Please see next pages for magnitude and phase plots.

Shown is the plot comparing the discrete computation of $x[n]$, shown on the top and bottom left of the figure, along with a comparison of the MATLAB FFT function, shown on the top and bottom right of the figure for MB3.3 (1). The results are in agreement for the magnitude of the expressions. The difference lies in the phase of the two signals. The first phase, resembling a saw tooth wave, takes the exponent from the expression starting at $n = -2$. In MATLAB, the FFT begins when $n = 0$, thus a difference is observed.

(a) determine the ideal impulse response $h_d(n)$ using [3.2]

$$x(n) \triangleq \mathcal{F}^{-1}[X(e^{j\omega})] = \frac{1}{2\pi} \int_{-\pi}^{\pi} X(e^{j\omega}) e^{j\omega n} d\omega$$

$$\begin{aligned} h_d(n) &= \frac{1}{2\pi} \int_{\omega_c}^{\pi} 0 e^{j\omega n} d\omega + \frac{1}{2\pi} \int_{-\omega_c}^{\omega_c} e^{-j\omega\alpha} e^{j\omega n} d\omega \\ &= \frac{1}{2\pi} \int_{-\omega_c}^{\omega_c} e^{j\omega(n-\alpha)} d\omega = -\frac{j}{2(n-\alpha)} e^{j\omega(n-\alpha)} \Big|_{-\omega_c}^{\omega_c} + C \\ &= \frac{1}{2j(n-\alpha)} e^{j\omega(n-\alpha)} \Big|_{-\omega_c}^{\omega_c} + C \\ &= \frac{1}{2j(n-\alpha)} [e^{j\omega_c(n-\alpha)} - e^{-j\omega_c(n-\alpha)}] + C \end{aligned}$$

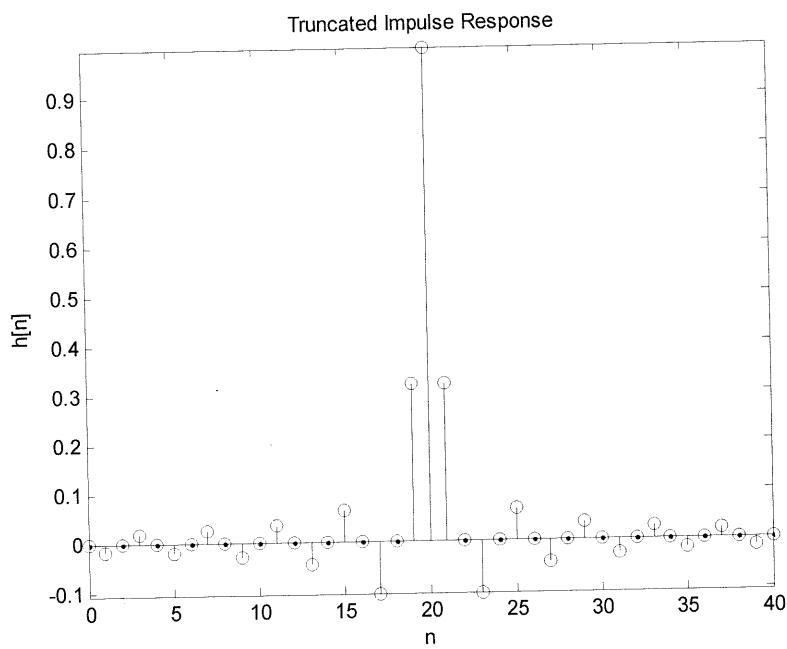

$$\text{NOTE: } \frac{1}{nx} \left[\frac{e^{inx} - e^{-inx}}{2i} \right] = \frac{\sin(nx)}{nx} = \text{sinc}(nx)$$

$$\begin{aligned} &= \frac{1}{\pi(n-\alpha)} \left[\frac{e^{j\omega_c(n-\alpha)} - e^{-j\omega_c(n-\alpha)}}{2j} \right] + C \\ &= \frac{\sin(\omega_c(n-\alpha))}{\pi(n-\alpha)} \left[\frac{\omega_c}{\alpha} \right] = \frac{\omega_c}{\pi} \frac{\sin(\omega_c(n-\alpha))}{\omega_c(n-\alpha)} \\ &= \frac{\omega_c}{\pi} \text{sinc}[\omega_c(n-\alpha)] \end{aligned}$$

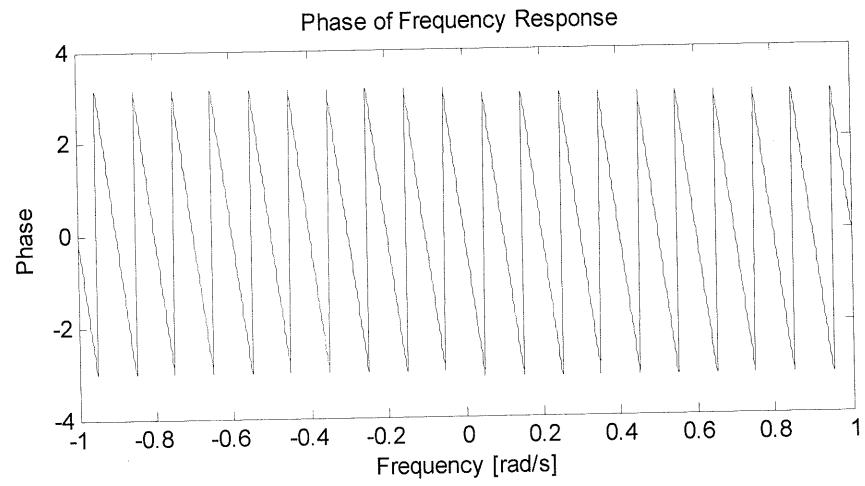

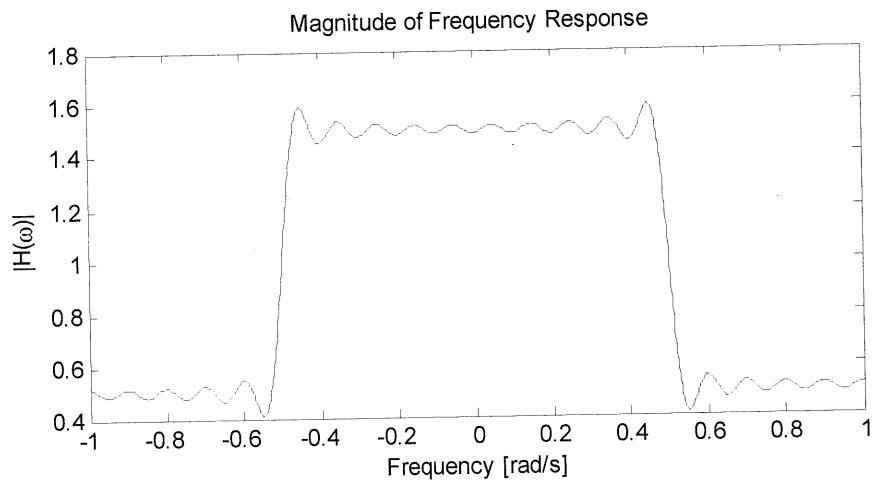

This is a low-pass filter. Ideally the filter would not have ringing in the edges (observed in the plots due to convolution with a sinc function).

Please see next page for plots.

TB.G.9 Consider the continuous-time signal

$$x_a(t) = \begin{cases} e^{-j2\pi F_0 t} & t \geq 0 \\ 0 & t < 0 \end{cases}$$

Freq. shifting

step fx. $e^{-j2\pi F_0 t} u(t)$

(A) Compute analytically the spectrum $X_a(F)$ of $x_a(t)$.

$$X_a(F) = \int_{-\infty}^{\infty} x_a(t) e^{j2\pi F t} dt$$

$$= \int_0^{\infty} e^{-j2\pi F_0 t} e^{j2\pi F t} dt = \int_0^{\infty} e^{-j2\pi t (F_0 + F)} dt$$

using shifting fx:

$$f(t) e^{j2\pi F_0 t} = F(F - F_0)$$

$$= \frac{1}{-j2\pi(F_0 + F)} e^{-j2\pi t (F_0 + F)} \Big|_0^{\infty} = \frac{1}{-j2\pi(F_0 + F)} [e^{-j2\pi(F_0 + F)0} - e^{-j2\pi(F_0 + F)\infty}]$$

$$\Delta = \frac{F}{2b+1}$$

$$= \frac{1}{j2\pi(F_0 + F)} //$$

$$e^{j\omega} = [\cos(\omega) + j\sin(\omega)]$$

$$e^{j\omega} = [\cos(\omega) + j\sin(\omega)]$$

(B) Compute analytically the spectrum of the signal $x(n) = x_a(nT)$

$$T = \frac{1}{F_s}$$

$$x(n) = \begin{cases} e^{-j2\pi F_0 n / F_s} & n \geq 0 \\ 0 & n < 0 \end{cases}$$

$$X(F) = \sum_{n=-\infty}^{\infty} x(n) e^{-j2\pi F n} \quad f = F/F_s$$

$$= \sum_{n=0}^{\infty} e^{-j2\pi F_0 n / F_s} e^{-j2\pi \frac{F}{F_s} n} = \sum_{n=0}^{\infty} e^{-j2\pi n / F_s (F_0 + F)}$$

what's a better method?

$$e^{j\omega} = ?$$

$$\text{for an infinite geometric series, } \sum_{n=0}^{\infty} e^{-j2\pi n / F_s (F_0 + F)} = \frac{e^{-j2\pi(0) / F_s (F_0 + F)} - e^{-j2\pi(\infty) / F_s (F_0 + F)}}{e^{-j2\pi / F_s (F_0 + F)} - 1} = \frac{1}{1 - e^{-j2\pi(F_0 + F) / F_s}} //$$

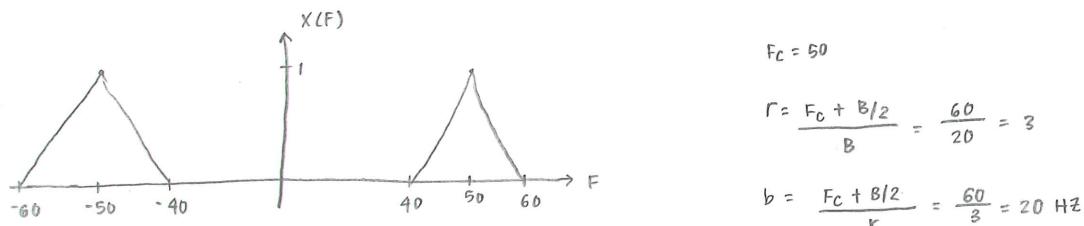

(C) Plot the magnitude spectrum $|X_a(F)|$ for $F_0 = 10$ Hz

(D) Plot the magnitude spectrum $|X(F)|$ for $F_s = 10, 20, 40$ and 100 Hz. (next page)

(E) Based on our plots, we observe aliasing when the frequency range is limited to $F = F_0 = F_s$. Here we are unable to see the entire signal in comparison with other plots.

-- tingling.

TB6.10 consider the sampling of the bandpass signal whose spectrum is shown. Determine the minimum sampling rate F_s to avoid aliasing.

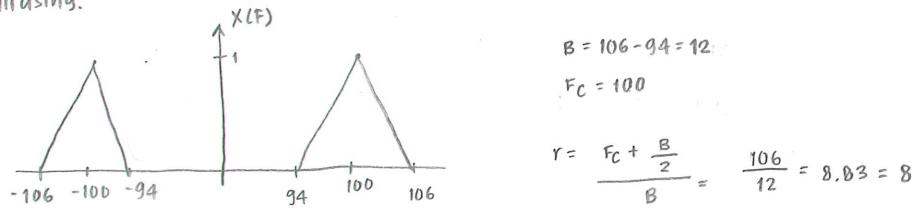

FOR aliasing to be avoided, sampling should be at least $F_s > 2B$. $F_s = 2b = 40 \text{ Hz}$

$$B = 60 - 40 = 20 \text{ Hz}$$

$$F_s = 2(20 \text{ Hz}) = 40 \text{ Hz} = 2b$$

the sampling frequency should at least be 40 Hz to avoid aliasing.

TB6.11 consider the sampling of the bandpass signal shown. Determine the minimum F_s to avoid aliasing.

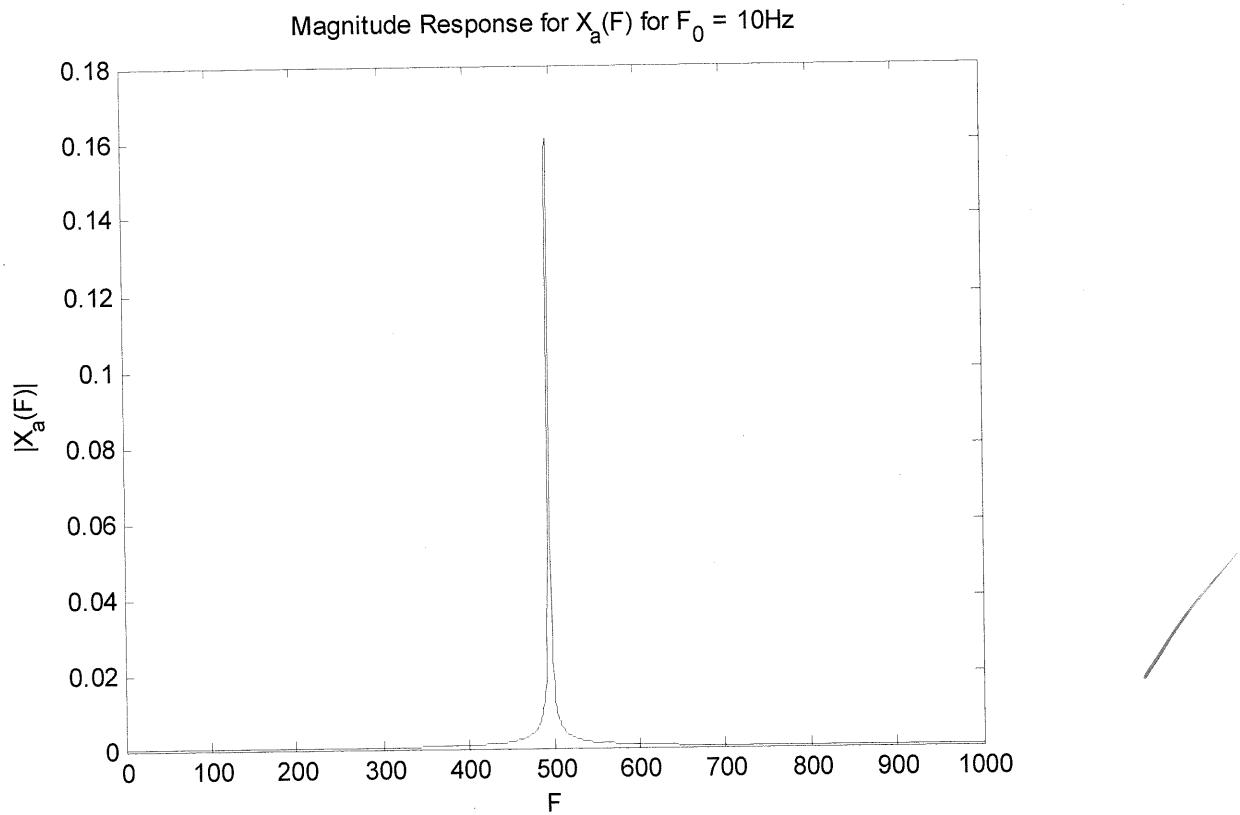

$$K_{\max} \leq \frac{F_h}{B} \quad K_{\max} = 8$$

$$F_{s\max} = \frac{2F_h}{K_{\max}} = \frac{2(106)}{8} = 26.5 \text{ Hz.}$$

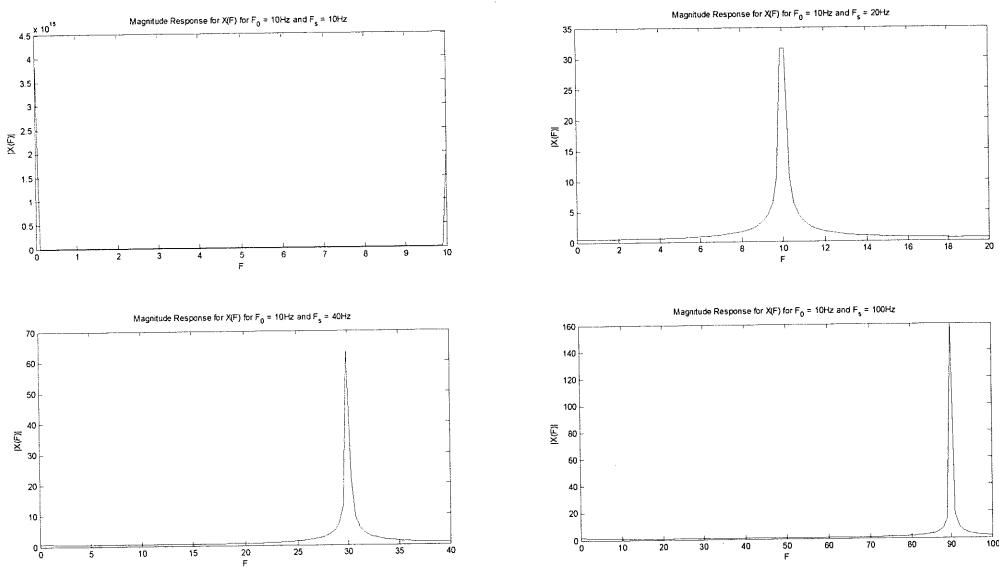

$$b = \frac{F_c + B/2}{r} = \frac{106}{8} = \frac{53}{4}$$

widens the BW.

P5) The plot shows the time advantage of using the Fast Fourier transform instead of Discrete Fourier transform. For data with a length of 2^{13} , FFT execution time is on the order of 10^{-4} seconds while using the DFT is almost one minute to compute.

Problem 2 17

Problem 3 20 19

Problem 4 17

Problem 5 20

Total 83

1. Given the following difference equation

$$y(n) = 0.6y(n-1) - 0.08y(n-2) + x(n)$$

Find

a) The Pulse Transfer function $H(z)$.

b) The impulse response.

c) The step response.

$$(A) Y(z) = 0.6 [z^{-1}Y(z)] - 0.08z^{-2}Y(z) + X(z)$$

using time-shifting property

$$x(n-k) \leftrightarrow z^{-k}X(z)$$

$$H(z) = \frac{Y(z)}{X(z)}$$

$$Y(z) [1 - 0.6z^{-1} + 0.08z^{-2}] = X(z)$$

$$H(z) = \frac{Y(z)}{X(z)} = \frac{1}{0.08z^{-2} - 0.6z^{-1} + 1} = \frac{A}{(z^{-1}-0.4)} + \frac{B}{(z^{-1}-0.2)}$$

$$\cancel{(z^{-1}-0.4)(z^{-1}-0.2)}$$

$$= z^{-2} - 0.2z^{-1} - 0.4z^{-1} + 0.08z^{-2}$$

$$A = \left. \frac{1}{(z^{-1}-0.4)} \right|_{z^{-1}=0.4} = \frac{1}{0.2} = 5$$

$$H(z) = \frac{1}{(1-\frac{1}{5}z^{-1})(1-\frac{2}{5}z^{-1})}$$

$$B = \left. \frac{1}{(z^{-1}-0.2)} \right|_{z^{-1}=0.2} = \frac{1}{-0.2} = -5$$

$$H(z) = \frac{5}{z^{-1}-0.4} - \frac{5}{z^{-1}-0.2} = \frac{5}{-0.4} \frac{1}{1-2.5z^{-1}} + \frac{5}{0.2} \frac{1}{1-5z^{-1}}$$

$$\text{CHECK: } \frac{5}{0.2-z^{-1}} = -\frac{5}{z^{-1}-0.2}$$

$$(B) n(n) = z^{-1}\{H(z)\}$$

$$\text{using Table 3.3 } a^n u(n) \leftrightarrow \frac{1}{1-a z^{-1}}, |z| > |a|$$

$$= -\frac{5}{0.4} (2.5)^n u(n) + \frac{5}{0.2} (5)^n u(n) // \quad \text{ROC: } |z| > |a|$$

$$n(n) = [z(\frac{2}{5})^n - (\frac{1}{5})^n] u(n)$$

(C) The step response is $x(z) = 1 //$

$$x(z) = \frac{1}{1-z^{-1}}$$

$$Y(z) = \frac{1}{(1-z^{-1})(1-\frac{1}{5}z^{-1})(1-\frac{2}{5}z^{-1})}$$

use P.F.E.

$$y(n) = \left[\frac{25}{12} + \frac{1}{4} \left(\frac{1}{5}\right)^n - \frac{4}{5} \left(\frac{2}{5}\right)^n \right] u(n)$$

2. a) Show that the following sequence

$$\sum_{n=0}^{\infty} n\alpha^n$$

can be represented in closed form as, for $|\alpha| < 1$

$$\frac{\alpha}{(1-\alpha)^2}$$

b) Determine the Discrete-Time Fourier Transform in closed form for the following sequence.

$$(A) \quad S_1 = \sum_{k=0}^{\infty} kx^k = 0 + x + 2x^2 + 3x^3 + \dots$$

$$x(n) = n(0.9)^n u(n)$$

$$-xS_1 = x \sum_{k=1}^{\infty} kx^k = 0 + x^2 + 2x^3 + 3x^4 + \dots$$

$$= x \underbrace{(1+x^2+x^3+\dots)}_{\frac{1}{1-x}}$$

$$(A) \quad \sum_{n=0}^{\infty} n\alpha^n \quad \text{using sum property, where } r=\alpha \text{ and } k=n$$

$$\begin{aligned} \text{for } \sum_{k=0}^n kr^k &= \frac{r + [n(r-1)-1]r^{n+1}}{(r-1)^2}, r \neq 1 \\ &= \frac{\alpha + [\infty(\alpha-1)-1]\alpha^{n+1}}{(\alpha-1)^2} \\ &= \frac{\alpha}{(1-\alpha)^2} \end{aligned}$$

$$S_1(1-x) = \frac{x(1)}{1-x}$$

$$S_1 = \frac{x}{(1-x)^2}$$

$$\begin{aligned} &\text{where } [\infty \alpha - \infty] = 0 \\ &= \frac{\alpha + [\infty \alpha^0 - \infty^0 - 1]\alpha^{n+1}}{(\alpha-1)^2} \end{aligned}$$

Here I meant to include the fact that $|\alpha| < 1$, $\alpha^{n+1} = -1$
which in that case when, say $\alpha = -1$ we get $\alpha^{n+1} = -1$

$$(B) \quad x(n) = n(0.9)^n u(n)$$

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x(n)e^{-j\omega n}$$

$$n\alpha^n u(n) \leftrightarrow \frac{az^{-1}}{(1-a z^{-1})^2}$$

$$= \sum_{n=-\infty}^{\infty} n(0.9)^n e^{-j\omega n} = n \quad [$$

$$X(z) = \frac{0.9z^{-1}}{(1-0.9z^{-1})^2}$$

$$\begin{aligned} &\text{similarly using the property above,} \\ &= \frac{0.9 + [n(0.9-1)-1]0.9^{n+1}}{(0.9-1)^2} = \frac{0.9 + [n(0.9-1)-n-1]0.9^{n+1}}{(0.9-1)^2} \\ &= \frac{0.9 + n0.9^{n+2} - n0.9^{n+1} - 0.9^{n+1}}{(0.9-1)^2} \end{aligned}$$

3

For terms, I meant to multiply with z^{-1} DFT T

$$\sum_{k=m}^n kr^k = \frac{r + [n(r-1)-1]r^{n+1}}{(r-1)^2}$$

because $0.9^0 = 0$

$$(B) \quad X(\omega) = \sum_{n=0}^{\infty} n(0.9)^n e^{-j\omega n} = \frac{0.9e^{-j\omega}}{(1-0.9e^{-j\omega})^2}$$

3. An analog signal

$$x_a(t) = \sin(480\pi t) + 3 \sin(720\pi t)$$

is sampled at 600 times per second. Determine

- a) the Nyquist sampling rate for $x_a(t)$.
- b) the folding frequency.
- c) the resulting discrete time signal, $x(n)$.
- d) Is there aliasing?

$$F_s = 600 \frac{1}{s} = 600 \text{ Hz}$$

$$(A) F_N = 2F_{\max} \quad F_1 = \frac{480}{2} = 240 \text{ Hz}$$

$$F_{\max} = F_2 \quad F_2 = \frac{720}{2} = 360 \text{ Hz}$$

$$F_N = 2(360) \text{ Hz} = 720 \text{ Hz} //$$

$$(B) F_f = \frac{F_s}{2} = \frac{600}{2} = 300 \text{ Hz} //$$

$$(C) x(n) = x_a(nt) = x_a\left(\frac{n}{F_s}\right)$$

$$= \sin 2\pi \left(\frac{240}{600}\right)n + 3 \sin 2\pi \left(\frac{360}{600}\right)n$$

$$= \sin 2\pi \left(\frac{8}{10}\right)n + 3 \sin 2\pi \left(\frac{12}{10}\right)n //$$

$$\text{We want } F_n < \frac{F_s}{2}, \text{ so for } F_2, \left(1 - \frac{3}{5}\right) = \frac{2}{5}$$

$$x(n) = \sin 2\pi \left(\frac{2}{5}\right)n + 3 \sin 2\pi \left(\frac{2}{5}\right)n //$$

- (D) Aliasing will occur for the second term where $f_2 = \frac{3}{5}$ since this is greater than F_s . We can avoid aliasing by setting $F_n < \frac{F_s}{2}$, which is reflected in the final result of (C). //

4. Using a 4-bit ADC quantize an analog input ranging from 0 to 5 volts.

- How many quantization levels.
- What is the resolution of the ADC.
- At an input of 3.2 volts what is the quantized value.
- At an input of 3.2 volts what binary code is produced.
- At an input of 3.2 volts what is the quantization error.

$$(A) L = 2^b = 2^4 = 64 \quad -3$$

$$(B) \Delta = \frac{\text{range}}{L-1} = \frac{V_{\max} - V_{\min}}{L-1} = \frac{5-0}{63} = 0.07936 \text{ V} = 79.36 \text{ mV/step}$$

$$(C) l \Delta = 3.2 \text{ V}$$

$$l = \frac{3.2 \text{ V}}{\Delta} = 40.32 \Rightarrow \text{floor}(l) = 40$$

$$(D) \begin{array}{ccccccccc} | & | & | & | & | & | & | \\ 128 & 64 & 32 & 8 & 4 & 2 & 1 \end{array} \quad 40 = 32 + 8$$

0011 0000

$$(E) e_q(n) = x_q(n) - x(n)$$

At 3.2 V, $l = 3.2$,

$$e_q(\Delta) = (40)(0.07936) = 3.1744$$

$$e_q(n) = 3.2 - 3.1744 = 0.0256$$

$$\text{max error} = \frac{\Delta}{2} = 0.0396 \text{ so, } e_q(3.2) = 0.0256 \text{ OK.}$$

5. Using the Reconstruction formula 6.1.20

a. find $x_a(t = 5.3)$

for $T=1$, $x(n)=n$, for the range of $n=3$ to $n=8$.

b. What value did you expect in part a?

c. How would you make your answer in part (a) more accurate?

$$x_a(t) = \sum_{n=3}^8 x(n) \frac{\sin(\pi/T)(t-nT)}{(\pi/T)(t-nT)} \quad x(n) = x_a(nT)$$

(A) $x_a(5.3) = ? \quad T=1 \quad x(n)=n \quad n=[3,8]$

$$\begin{aligned} x_a(t) &= \sum_{n=3}^8 x(n) \frac{\sin(\pi)(t-n)}{(\pi)(t-n)} = \sum_{n=3}^8 n \frac{\sin(\pi)(t-n)}{\pi(t-n)} \\ &= (3) \frac{\sin(\pi)(5.3-3)}{\pi(5.3-3)} + (4) \frac{\sin(\pi)(5.3-4)}{\pi(5.3-4)} + (5) \frac{\sin(\pi)(5.3-5)}{\pi(5.3-5)} \\ &\quad + (6) \frac{\sin(\pi)(5.3-6)}{\pi(5.3-6)} + (7) \frac{\sin(\pi)(5.3-7)}{\pi(5.3-7)} + (8) \frac{\sin(\pi)(5.3-8)}{\pi(5.3-8)} \end{aligned}$$

(In other words,

$$\begin{aligned} &3 \operatorname{sinc}[\pi(5.3-3)] + 4 \operatorname{sinc}[\pi(5.3-4)] + 5 \operatorname{sinc}[\pi(5.3-5)] \\ &+ 6 \operatorname{sinc}[\pi(5.3-6)] + 7 \operatorname{sinc}[\pi(5.3-7)] + 8 \operatorname{sinc}[\pi(5.3-8)] \\ &= 3(0.1111916) + 4(-0.1980) + 5(0.8584) + 6(-0.3679) + 7(-0.1515) + 8(0.09539) \\ &= 5.74582 \checkmark \end{aligned}$$

(B) For $x(n)=n$, we could have expected to have a value of 5.3 by direct application of $x_a(t=5.3) = x(n) = x_a(nT)$.

(C) To make the answer in (A) more accurate, i.e. be closer to the expected 5.3, we can try to interpolate at more points.

$$X(7) = [B(6) - B(7)] W_8^0 = \left(1 + \frac{\sqrt{2}}{2}\right) + j\frac{\sqrt{2}}{2}$$

(B) The main advantage of FFT vs. DFT is the amount of time to compute.

Complexity for FFT is $\frac{N}{2} \log_2 N$ vs. N^2 for DFT.

3. Given the following difference equation

$$y(n) = y(n-1) - \frac{1}{2}y(n-2) + x(n) - x(n-1) + x(n-2)$$

- a) Find the Pulse Transfer function $H(z)$. Show all work.
- b) Draw the Direct Form 1 filter realization of the system labeling all of the relevant coefficients.
- c) Draw the Direct Form 2 filter realization of the system labeling all of the relevant coefficients.

(A)

$$Y(z) = z^{-1}Y(z) - \frac{1}{2}z^{-2}Y(z) + X(z) - z^{-1}X(z) + z^{-2}X(z)$$

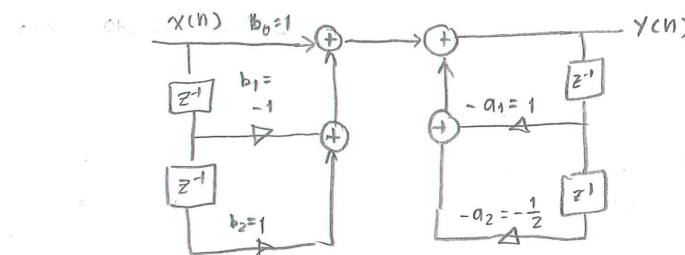

$$H(z) = \frac{Y(z)}{X(z)}$$

$$Y(z)[1 - z^{-1} + \frac{1}{2}z^{-2}] = X(z)[1 - z^{-1} + z^{-2}]$$

$$= 1 + 1 + 0 + 0 + 0 + 0 + 0 + 0 = 2$$

$$X(k=1) = 1e^0 + 1e^{-j\pi/4} + 0e^{-j2\pi/4} + \dots = 1.707 - j0.707$$

Rest Terms zero

$$X(k=2) = 1e^0 + 1e^{-j\pi/2} + 0e^{-j4\pi/4} + \dots = 1 - j$$

$$X(k=3) = 1e^0 + 1e^{-j3\pi/4} = 0.293 - j0.707$$

$$X(k=4) = 1e^0 + 1e^{-j\pi/4} = 0$$

$$X(k=5) = 1e^0 + 1e^{-j5\pi/4} = 0.293 + j0.707$$

$$X(k=6) = 1e^0 + 1e^{-j6\pi/4} = 1 + j$$

$$X(k=7) = 1e^0 + 1e^{-j7\pi/4} = 1.707 + j0.707$$

b) Magnitude of each Term $X(k)$ by

$$|X(k)| = \sqrt{Re^2 + Im^2}$$

$$|X(0)| = 2$$

$$|X(1)| = 1.85$$

$$|X(2)| = 1.41$$

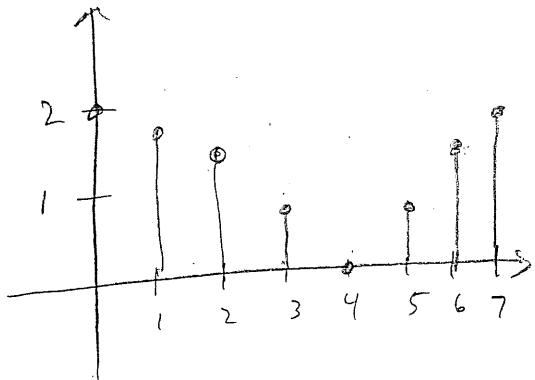

$$|X(3)| = 0.765$$

$$|X(4)| = 0$$

$$|X(5)| = 0.765$$

$$|X(6)| = 1.41$$

$$|X(7)| = 1.85$$

c) Phase of the DFT
